# Where does the concept of risk come from?

## The risk management of Arnobius (about 440 AC)

God exists	Goed does not exist
Believing in God	+
Not believing in God	-

# Variants of Risks

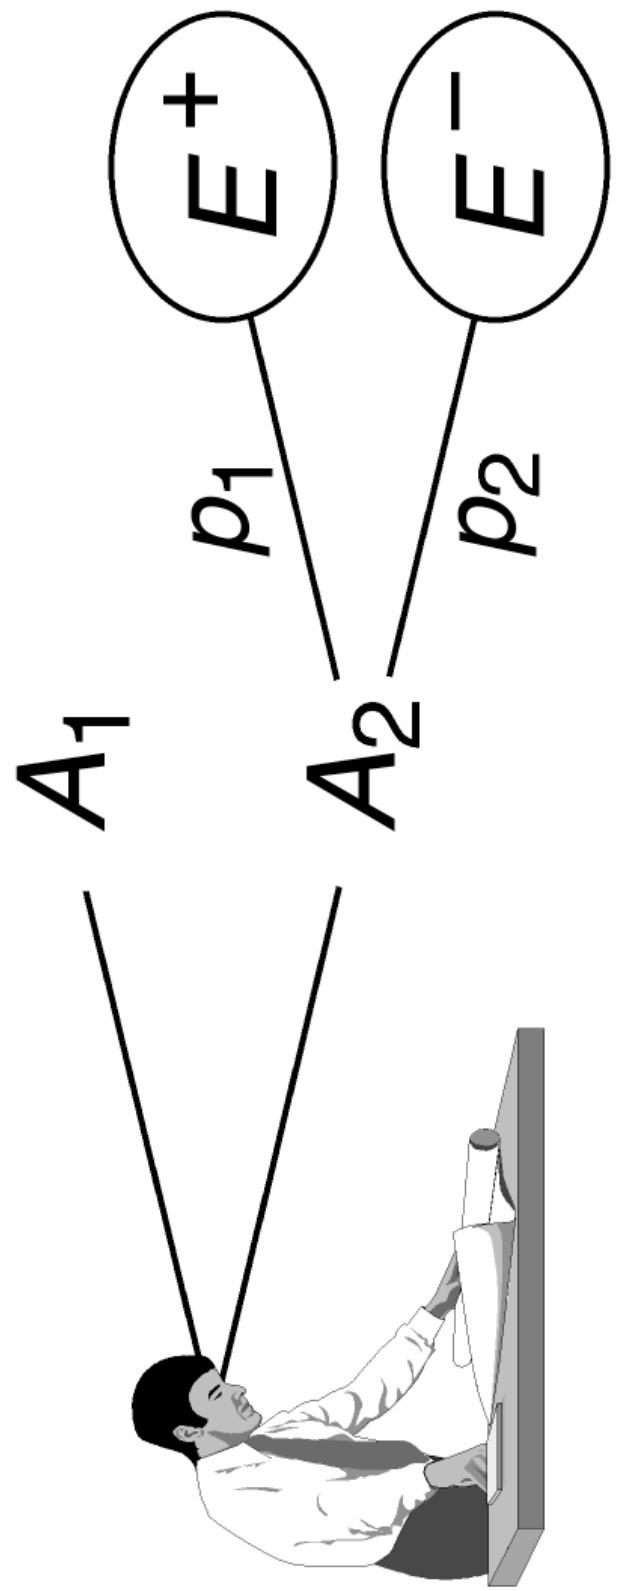

## Formal Definition of Risk Situations

An Elementary Risk Situation is given by the following:

- There must be an agent having the choice between at least two alternatives  $A_1$  and  $A_2$ .
- With the choice of one of the two alternatives, uncertainty arises: which event of two events  $E^+$  or  $E^-$  will be the outcome of the chosen alternative.
- The agent considers the value,  $v(E)$ , of at least one uncertain event as a loss at least relative to the other event(s).

# Variants of Risks

## Formal Definition of Risk Situations

# Variants of Risks

## Formal Definition of Risk Situations

An General Risk Situation is defined as the following:

- An agent has the choice between different alternatives from a set  $A = (A_1, \dots, A_i, \dots, A_n)$ .
- For each alternative  $A_i$ , there is a set of possible events  $E_i = (E_{i,1}, \dots, E_{i,n_j})$ .
- For each alternative  $A_i$ , there is a probability vector  $\rho_i = (\rho_{i,1}, \dots, \rho_{i,n_j})$ . The probability  $\rho_{i,j}$  denotes the probability of  $E_{i,j}$  if  $A_i$  is chosen,  $0 < \rho_{i,j} < 1$  for at least one  $i$  and  $j$ .

# Risk ≠ Danger

## Risk is different from danger

- When we talk about risk, we must have different strategies/alternatives we can choose and at least one negative outcome is linked to the alternatives
- Tsunami management (deciding where to allow settlements) is risk management
- The impact of asteroids with a diameter of at least 1 km is a danger

# Risk is “primitive”, an elementary concept

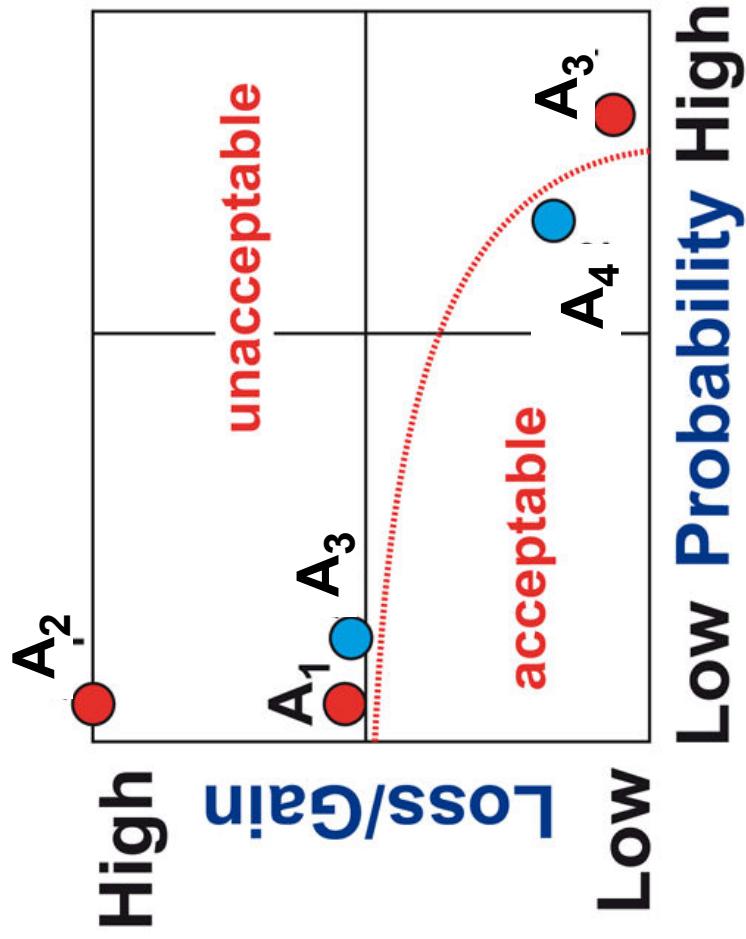

- (Almost) Everybody knows what is meant with risk
- It is an elementary concept in the sense of Kant
- Risk assessment and risk judgments provide evaluations

# Variants of Risks

1. **Expected losses** (e.g. the expected number of people killed; insurances are/have been using this concept)
2. **Expected value** (the expected value of gains/losses; the banks are using this concept in the credit business)
3. **Largest Loss** (concerned people are using this concept)
4. **Combined evaluation of**
  - The **costs** of getting access to an alternative  $A = (A_1, \dots, A_j, \dots, A_n)$
  - The **outcomes** that may result, if one alternative is chosen ( $E(A_i) = (E_{i,1}, \dots, E_{i,j}, \dots, E_{i,n})$ )
  - The **probabilities**  $\rho_{i,j}$  that certain events occur, if a certain alternative is chosen
5. For understanding differences in risk assessment and risk judgments it is important to distinguish between **pure risks** and **speculative risk**. Pure risk is only looking at the negative aspects. Speculative risk on positive and negative aspects.

# Variants of Risks

Risk judgments are combining losses/gains and the probability of their occurrence

## Steps of Risk Assessment (in toxicology; e.g. for heavy metals, POPs, nanotech particles)

1. Defining the risk situation
2. Defining the negative effects
3. Assessing the dose-response relationship
4. Assessing the exposure
5. Characterizing the risk

# Risk Assessment Methods

The risk (e.g. the expected health effects, DALYS) can be assessed by

- Epidemiological Studies
- Animal Experiments
- Low-dose Human Experiments
- Expert Judgments for Cases
- (Simulation)
- ...

# Risk assessment ≠ risk perception

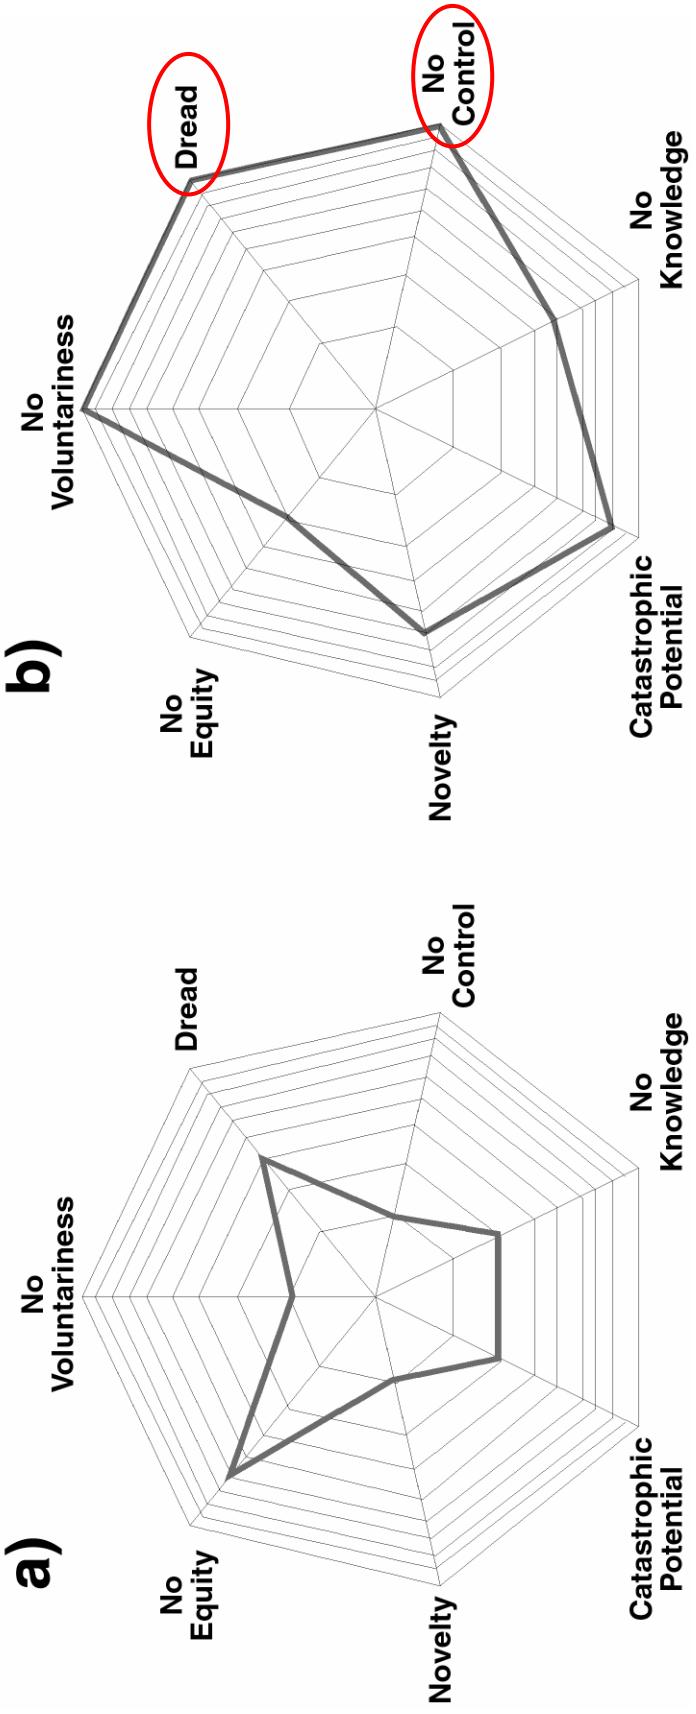

- Risk assessment is a science based procedure and evaluation. It is provided by (groups) of scientists
- Risk perception is based on a psychological process. It is provided by an individual (or by a group).

# Risk Perception:

## What's happening in the mind of people

Psychological, risks (risk situation) have a „personality“, i.e.

can be characterized by different aspects (Slovic et al. 1979)

## The cases: Heavy metals

# The Cases – Heavy Metals

## What are Heavy Metals?

- "Heavy metals" are chemical elements with a specific gravity that is at least 5 times the specific gravity of water.
- Antimony, **Arsenic**, Bismuth, Cadmium, Cerium, Chromium, Cobalt, Copper, Gallium, Gold, Iron, **Lead**, Manganese, **Mercury**, Nickel, Platinum, Silver, Tellurium, Thallium, Tin, **Uranium**, Vanadium, and Zinc

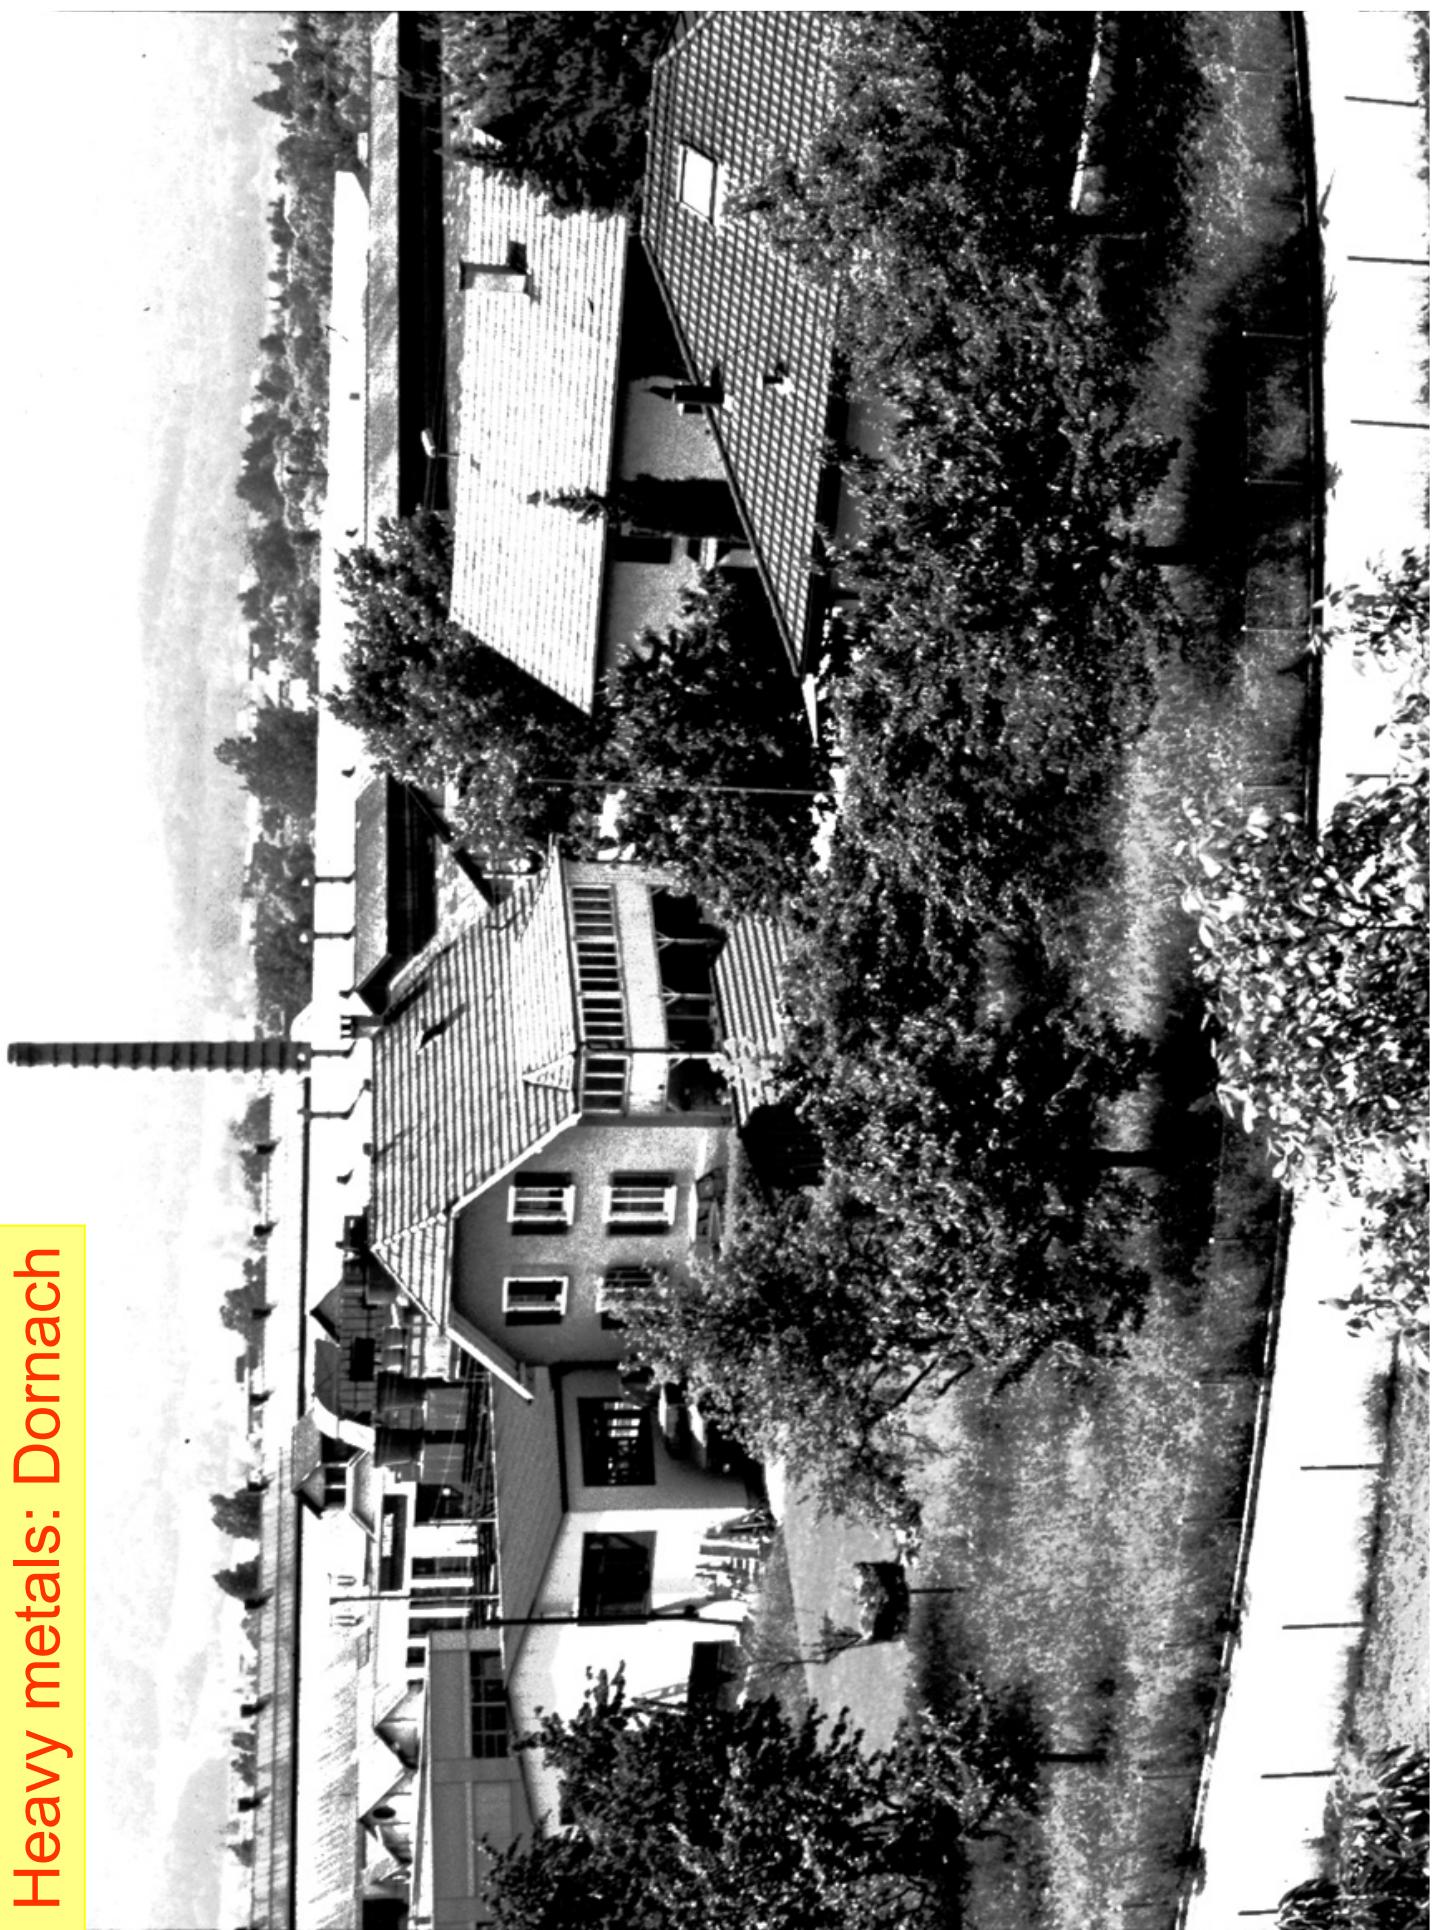

U.S. Department of Labor <http://www.osha.gov/SLTC/metalsheavy/index.html>

# The Cases – Heavy Metals

Where do they come from?

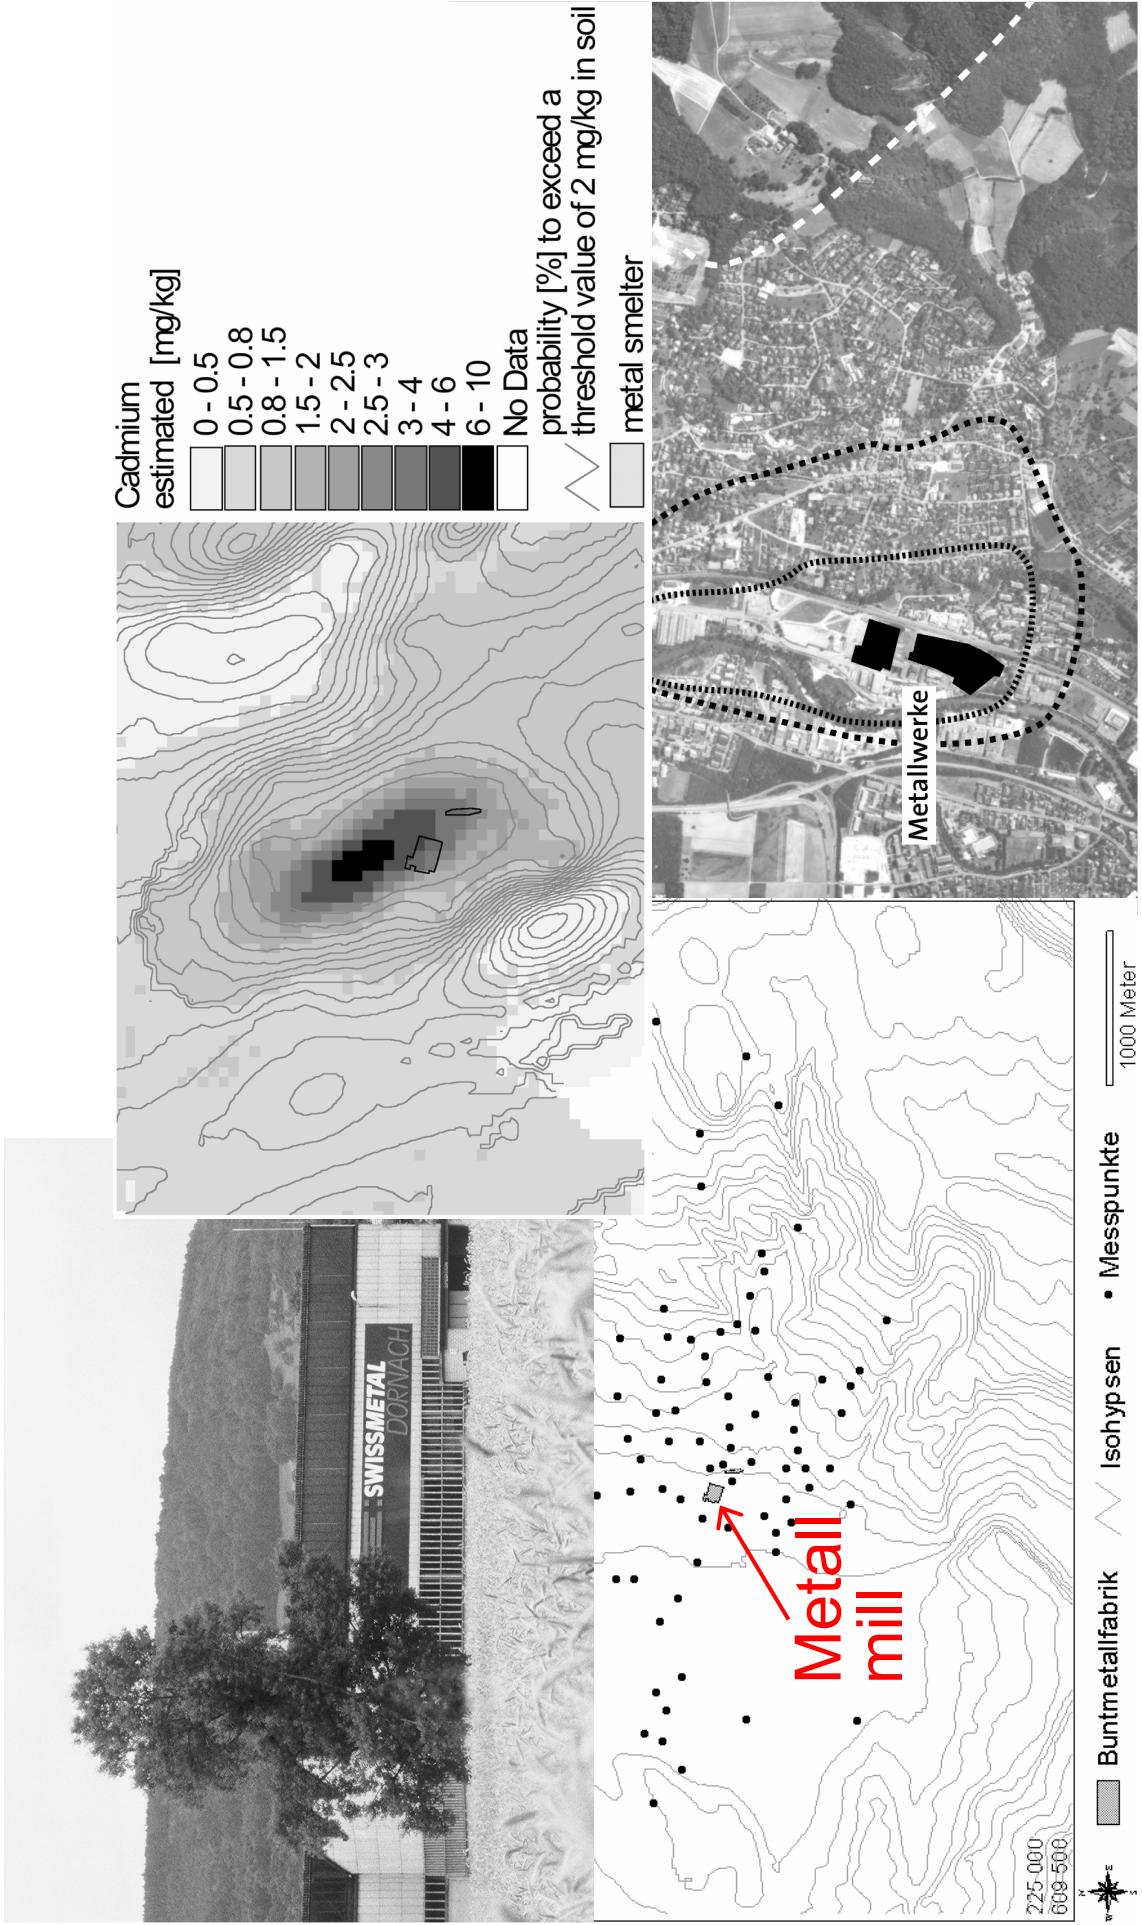

- Geogene background layer
- Mining
- Industrial production (metal production, smelting, galvanic industry, etc)
- Combustion processes
- Waste, waste water
- Agricultural products
- Smoking
- ...

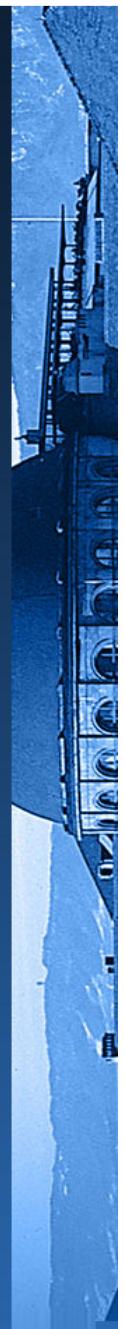

Heavy metals: Dornach

## Heavy metals

# The situation in Dornach: “Large scale” contamination with Cadmium, Copper, and Zinc

# The Cases – Heavy Metals

## Where do we find them in the environment?

In all environmental compartments and species!

- Heavy metals are natural components of the Earth's crust.
- Heavy metals can enter a water supply by industrial and consumer waste, or even from acid rain breaking down soils and releasing heavy metals into streams, lakes, rivers, and groundwater.

Source: <http://www.lenntech.com/heavy-metals.htm>

# The Cases – Heavy Metals

## What negative effects do they have?

- Heavy metals become toxic when they are not metabolized by the body and accumulate in the soft tissues (copper, selenium, zinc etc. are essential elements to maintain metabolic processes).
- Possible symptoms of toxication are:
  - Cramping, nausea, and vomiting
  - Pain
  - Sweating
  - Headaches
  - Difficulty breathing
  - Impaired cognitive, motor, and language skills
  - Mania
  - Convulsions
  - ...

# The Cases – Heavy Metals

Risk assessment of some Heavy Metals; Swiss threshold values; note the bioavailable part provides other data

Category of utilization	Total concentration (mg/kg dried matter for soil up to 15 % Humus, mg/dm <sup>3</sup> for soil over 15 % humus)			Sampling Depth (in cm)
	Lead (Pb)	Cadmium (Cd)	Copper (Cu)	
Agri- and Horticulture	2'000	30	1'000	2'000
Garden and Allotment	1'000	20	1'000	2'000
Play- grounds	1'000	20	Š	Š

Source: Swiss Federal Council, 1998

# The Cases – Heavy Metals

## Conclusions on the assessment

- The risk of most metals are well assessed
- No real disputes about toxicity (Paracelsus principle still dominating)
- The exposure to and the impact of interaction among different metals are not well known
- High tech technological industrial production can easily reduce the emission of heavy metals

# The Cases – Heavy Metals

## Risk Perception

Critical questions investigated:

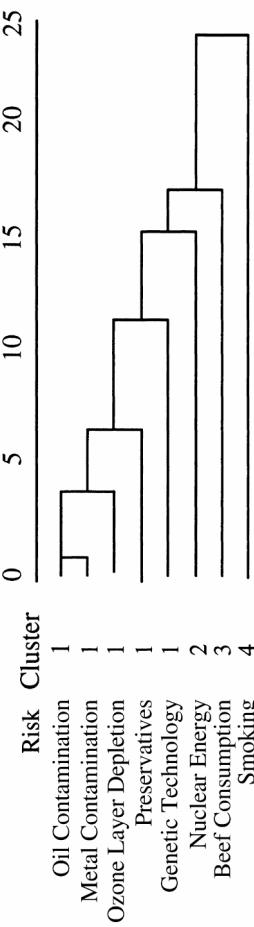

- Is the risk of heavy metals appropriately perceived?
- What characteristics are linked with heavy metals?
- How does the judgment of people concerned differ from the judgment non-concerned people?
- When do people become very sensitive?

# The Cases – Heavy Metals

## Risk Perception

Critical questions investigated:

- Is the risk of heavy metals appropriately perceived?
- What characteristics are linked with heavy metals?
- How does the judgment of people concerned differ from the judgment non-concerned people?
- Similar to oil, ozone layer, and preservatives
- Medium with respect to controllability
- No (or indifferent) to dread
- No catastrophic potential
- When do people become very sensitive?

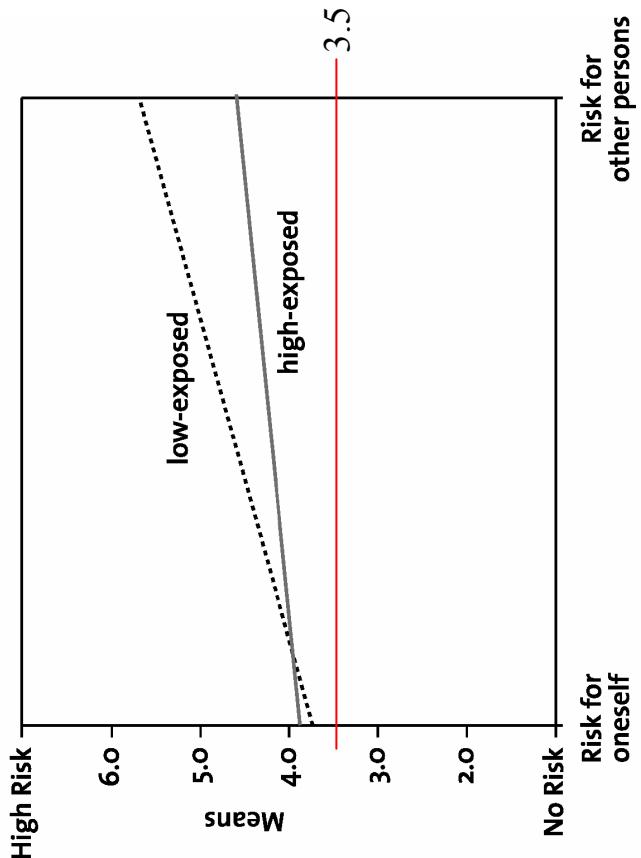

# The Cases – Heavy Metals

## Risk Perception

Critical questions investigated:

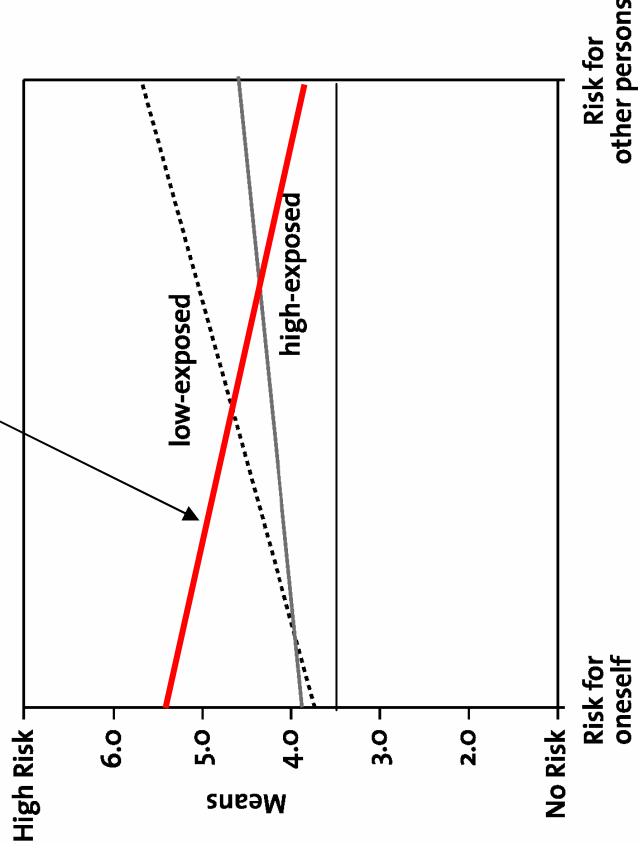

- Is the risk of heavy metals appropriately perceived?
- What characteristics are linked with heavy metals?
- How does the judgment of people concerned differ from the judgment non-concerned people?
- When do people become very sensitive?

# The Cases – Heavy Metals

## Risk Perception

This should be the rating  
of the exposed group

Critical questions investigated:

- Is the risk of heavy metals appropriately perceived?
- What characteristics are linked with heavy metals?
- How does the judgment of people concerned differ from the judgment non-concerned people?
- When do people become very sensitive?

- The illusion of control seems to be at work at exposed people!

# The Cases – Heavy Metals

## Conclusions

- The toxicity of heavy metals is well explored (classical risk assessment works)
- Exposure results from multiple sources (food, air, smoking, water, ....)
- The dose-response curves are well known
- There's a worldwide consensus that severe environmental standards are beneficial in a multiple way (from health costs to industrial competitiveness)
- People (in Central Europe) are reasonable judging the risk of heavy metals
- There are interesting “paradoxes” of judging oneself and others

**ETH**

Eidgenössische Technische Hochschule Zürich  
Swiss Federal Institute of Technology Zurich

# The case **Persistent organic pollutants**

## The Cases – **POPs** Persistent Organic Pollutants What are POPs?

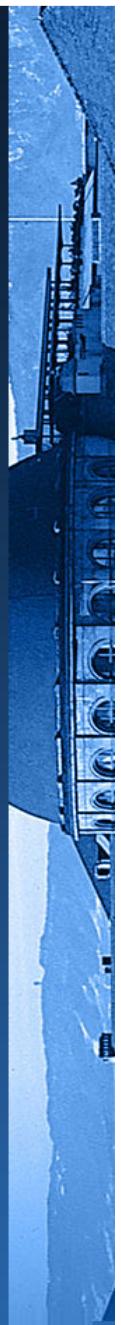

- POPs are chemicals that resist degradation (critical times are 2 months in water, 5 months in soil; bioaccumulation about 5000)
- There are 100,000 registered chemicals; 30,000 to 70,000 in daily use
- Well-known examples are chlorine compounds (e.g. DDT, PCDDs, PCDFs, lindane, dieldrin, endrin, PCB)
- Also carcinogenic polycyclic aromatic hydrocarbons (PAHs, Benz-a-pyrene) are considered POPs
- Description see Stockholm Convention on POPs, signed by 150 countries on 17 May 2004, <http://www.pops.int/>

# The Cases – **POPs** Persistent Organic Compounds

## Where do they come from?

- POPs are caused by many human activities including chemical industry (color, chlorine production) combustion for energy production and transportation, industrial processes, and agricultural uses of pesticides
- Historically, organochlorine insecticides (biocides) and the food chain were the primary sources of human uptake

# The Cases – POPs Persistent Organic Compounds

## Where do we find them?

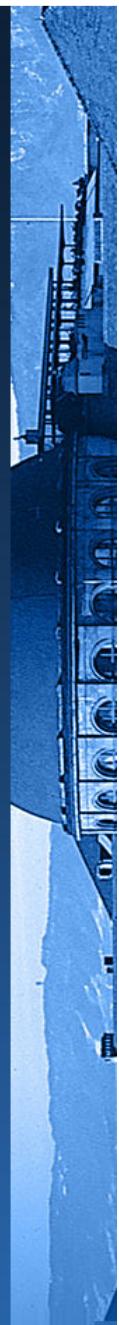

- 300 million tons of synthetic compounds are used each year
- 140 million tons fertilizers
- 5 million tons pesticides
  
- POPs can be found in all environmental compartments and are accumulated particularly in fat tissues
  - Long travel distances in water
  - Many are semi-volatile, long-distance transport in air

# The Cases – POPs Persistant Organic Compounds

## What negative effects do they have?

- POPs have negative effects primarily in aquatic, soil, and organismic systems
- The are bioaccumulated in *fat tissues* (animal fat)
- WHO estimates that 3 million farmers experience severe poisoning by pesticides, about 18,000 die each year
- POPs cause multiple effects in human and animals including
  - Cancer
  - Neurologic diseases
  - Immune system disorders,
  - Birth effects, infertility

# POPs Persistant Organic Compounds

## Risk assessment of some POPs

- Human risks: 90% of uptake of the (known) 15 to 50 critical chemicals occur by diet (fish, meat, ...)
- Human risk assessment comes to its limits
  - High number of chemicals
  - Their interaction
  - Metabolic processes
  - Their “efficiency”, they harm by very low concentration
- Environmental risks
  - POPs are a major threat of water quality
  - Ecosystems: The mutual interaction of thousands of chemicals in the environment with millions of biological species will ultimately determine whether a given pollutant (mixture) leads to marginal or catastrophic ecological consequences. (Schwarzenbach et al., 2006, Science p. 1075)

# Conclusions on POPs

- We are starting to get a good knowledge about dangerous POPs (see Stockholm convention)
- Classical risk assessment comes to its limits in ecosystem health (but also in human health; the OECD concept of systemic risk seems appropriate)
- There is evidence of illusionary control of concerned people (sport fisherman ignore the increased risk)
- Trust, dread, and the stigmatization matter
  - The example of municipal waste incineration in Switzerland and the U.S.
    - In Switzerland 99% of all municipal waste (which can nor be efficiently recycled such as paper, metal, glass, batteries) is burned
    - There is an old incinerator Josephstrasse in operation since 1904. Now a fancy upper middle-class Loft-living area with 10'000 residents is booming just in the neighbourhood (distance less than 100 meters) has been build (The living quality in the City of Zurich is worldwide ranked between 1 and 3).

## Missing trust in incinerator companies and fear of dioxine and toxic ash is preventing incinerators in GB and the U.S.

# The case Nanotech particles

# Nanotechnology

- A nanometre (nm) is one thousand millionth of a metre (i.e.  $10^{-12}$  m; the **length of 4 neighboured metal atoms**)
- People are interested in the nanoscale (0.2 - 100 nm) because it is at this scale that the properties of materials can be very different from those at a larger scale, engineering on the scale of atoms
- Properties of materials can be different at the nanoscale
  - Relatively **larger surface**
    - Quantum effects can begin to dominate the behavior of matter

Zur Anzeige wird bei QuickTime™ "u. Dekompressions benötigt".

# The Case Nanotech Particles

## What are Nanotech Particles?

- Nanoparticles (nanopowders, nanoclusters, nanocrystals) are particles with at least one dimension less than 100 nm.
- Nanostructures can be divided in
  - Nanofilms
  - Nanowires
  - Nanotubes
  - Nanoparticles
- Typical examples are
  - Nano-titanium, -taniumdioxide, -alumina, -zinc, -silver, carbon black, and carbon nanotubes

# The Case Nanotech Particles

## where do they come from?

Nanoparticles derivation can be divided into:

- I. Nonengineered, combustion-derived nanoparticles (like diesel soot),
- II. Manufactured (engineered) nanoparticles like carbon nanotubes
- III. Nonengineered, naturally occurring nanoparticles from volcanic eruptions, atmospheric chemistry etc.

# Current applications of engineered Nanoparticles

Engineered nanoparticles are intentionally designed and created with physical or chemical properties to meet the needs of specific applications.

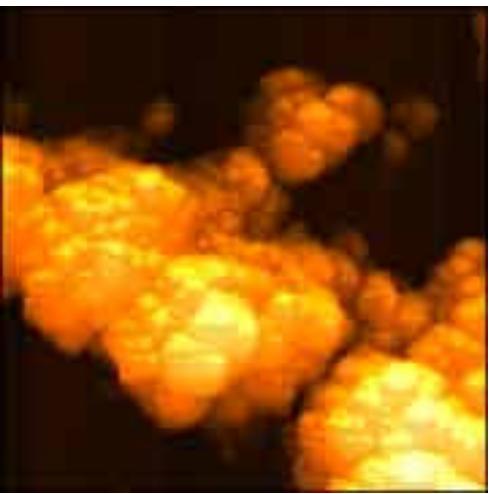

Figure:  
Carbon black, commonly used to enhance the properties of manufactured rubber, is clearly visualized using the NANO-R™.  
[http://www.pacificnano.com/nanoparticles\\_applications-for-nanoparticles.html](http://www.pacificnano.com/nanoparticles_applications-for-nanoparticles.html)

# Current applications of nanoparticles (cont.)

Properties	Applications/potential emission sources to the environment
■ Electronic	High performance and smaller components, e.g., capacitors for small consumer devices such as mobile phones; displays that are cheaper, larger, brighter, and more efficient; high conductivity materials
■ Optical	Anti-reflection coatings; tailored refractive index of surfaces; Light based sensors for cancer diagnosis
■ Magnetic	Increased density storage media; nano-magnetic particles to create improved detail and contrast in MRI images
■ Thermal	Enhance heat transfer from solar collectors to storage tanks; Improve efficiency of coolants in transformers
■ Mechanical	Improved wear resistance; new anti-corrosion properties; New structural materials, composites, stronger and lighter

# Current applications of nanoparticles (cont.)

Properties	Applications/potential emission sources to the environment
■ Energy	High energy density and more durable batteries; hydrogen storage applications using metal nano-clusters; Electrocatalysts for high efficiency fuel cells; Renewable energy, ultra high performance solar cells; Catalysts for combustion engines to improve efficiency, hence economy
■ Biomedical	Antibacterial silver coatings on wound dressings; sensors for disease detection (quantum dots); programmed release drug delivery systems; “interactive” food and beverages that change color, flavor or nutrients depending on a diner’s taste or health
■ Environmental	Clean up of soil contamination and pollution, e.g. oil; Biodegradable polymers; Aids for germination; treatment of industrial emissions; more efficient and effective water filtration
■ Surfaces	Dissolution rates of materials are highly size dependant; activity of catalysts, coatings for self cleaning surfaces, Pilkington’s glass for example.
■ Personal care	Effective clear inorganic sunscreens

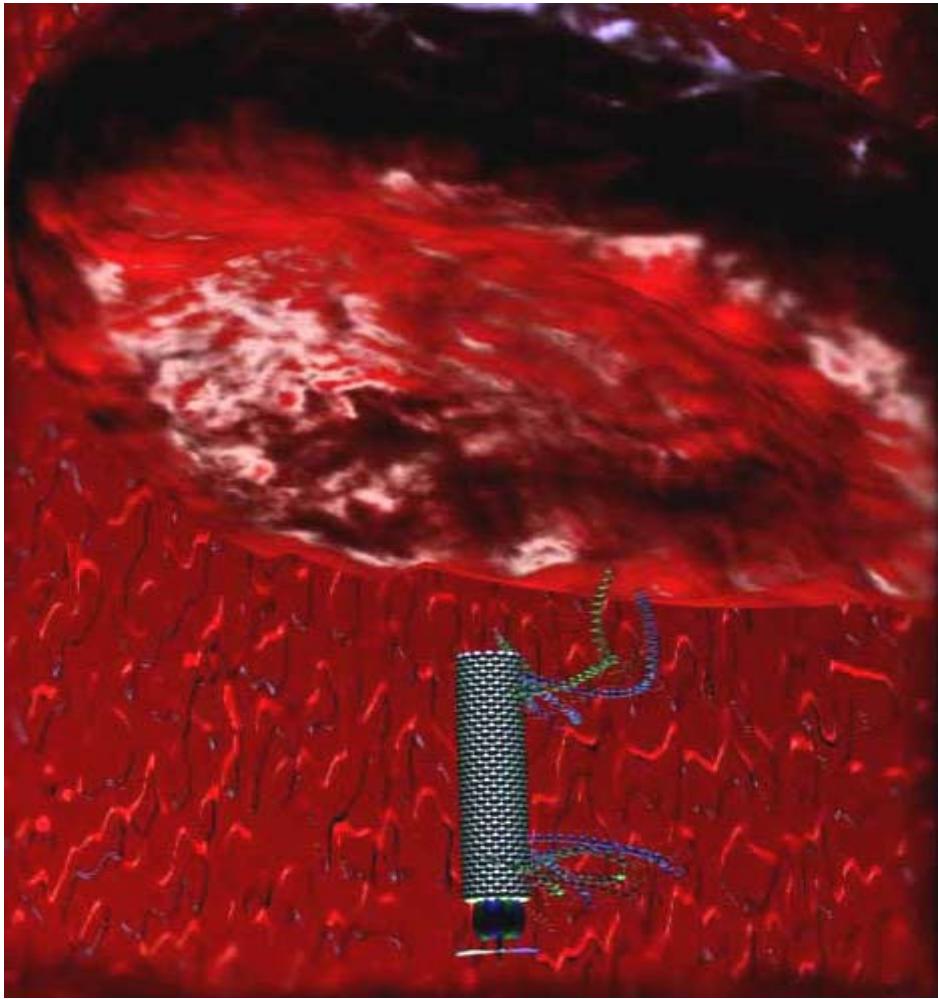

[http://www.malvern.com/LabEng/industry/nanotechnology/nanoparticle\\_applications.htm](http://www.malvern.com/LabEng/industry/nanotechnology/nanoparticle_applications.htm)

Scientists at Rutgers University believe that nano-sized robots will be injected into the bloodstream in 2020, and administer a drug directly to an infected cell.

This robot has a carbon nanotube body, a bio-molecular motor that propels it and peptide limbs to orient itself.

Because it is composed of biological elements such as DNA and proteins, it will be easily removed from the body.

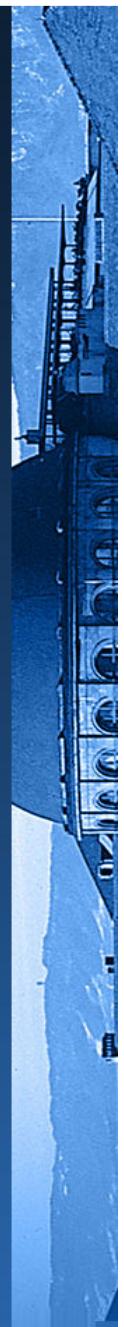

([http://bionano.rutgers.edu/Mavroidis\\_Final\\_Report.pdf](http://bionano.rutgers.edu/Mavroidis_Final_Report.pdf))

# The Cases – Nanotech Particles

## Where do we find them in the environment?

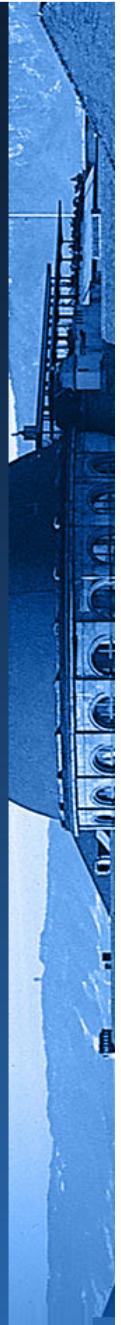

- Combustion-derived nanoparticles
  - Urban exposure
  - Exposure to nanoparticles derives mostly from traffic, e.g. diesel soot, which is well-known to produce a range of adverse human health effects.
- Engineered nanoparticles
  - Occupational exposure
  - In the search for novel nanoparticles a whole new range of different nanoparticle types are being produced in small quantities for experimental purposes or in bulk.

# The Cases – Nanotech Particles (cont.)

## Where do we find them in the environment?

- Engineered nano-particles (cont.)
  - Manufacture exposure
  - The release of nano-particles in industrial effluent could lead to contamination of ecosystems. Eventually, as nano-particles are mass-produced and introduced into more products, there will inevitably be a risk of release of nano-particles into the environment.

# Nano-tech Particles

## What negative effects do they have?

The potential health risk from engineered nanoparticles is largely unknown:

- Exposure to extremely fine particles, has been associated with increased morbidity and mortality from lung and cardiovascular disease.
- Exposure from traffic, e.g. diesel soot is well-known to produce a range of adverse human health effects. These seems to occur in well-defined, already-ill populations, that include asthmatics and those with smokers lung disease – COPD (Chronic Obstructive Pulmonary Disease). However, the biggest adverse health impact seems to be in people with cardiovascular (heart and circulatory) disease who suffer from increased hospitalisations and deaths.

# Nanototech Particles

## What negative effects do they have? (cont.)

- Interactions between nanoparticles and the skin is a special case since nanoparticles are already present in e.g. sunblock cream. There is little known about the transfer of nano-particles across the skin or their ability to harm skin and so much more research is needed in this area
- Nano-particles are also present in processed food, but it isn't known whether they produce adverse effects e.g. on the gut
- All of these findings are new and so although we do understand in part the action of these types of environmental nano-particles, but we are far from having a complete picture

# The Cases – Nanotech Particles

## Risk assessment of Nanotech Particles

The traditional risk assessment methodology which consists of

1. Defining the risk situation
2. Hazard identification
3. Dose-response relationship identification
4. Exposure assessment
5. Risk characterization

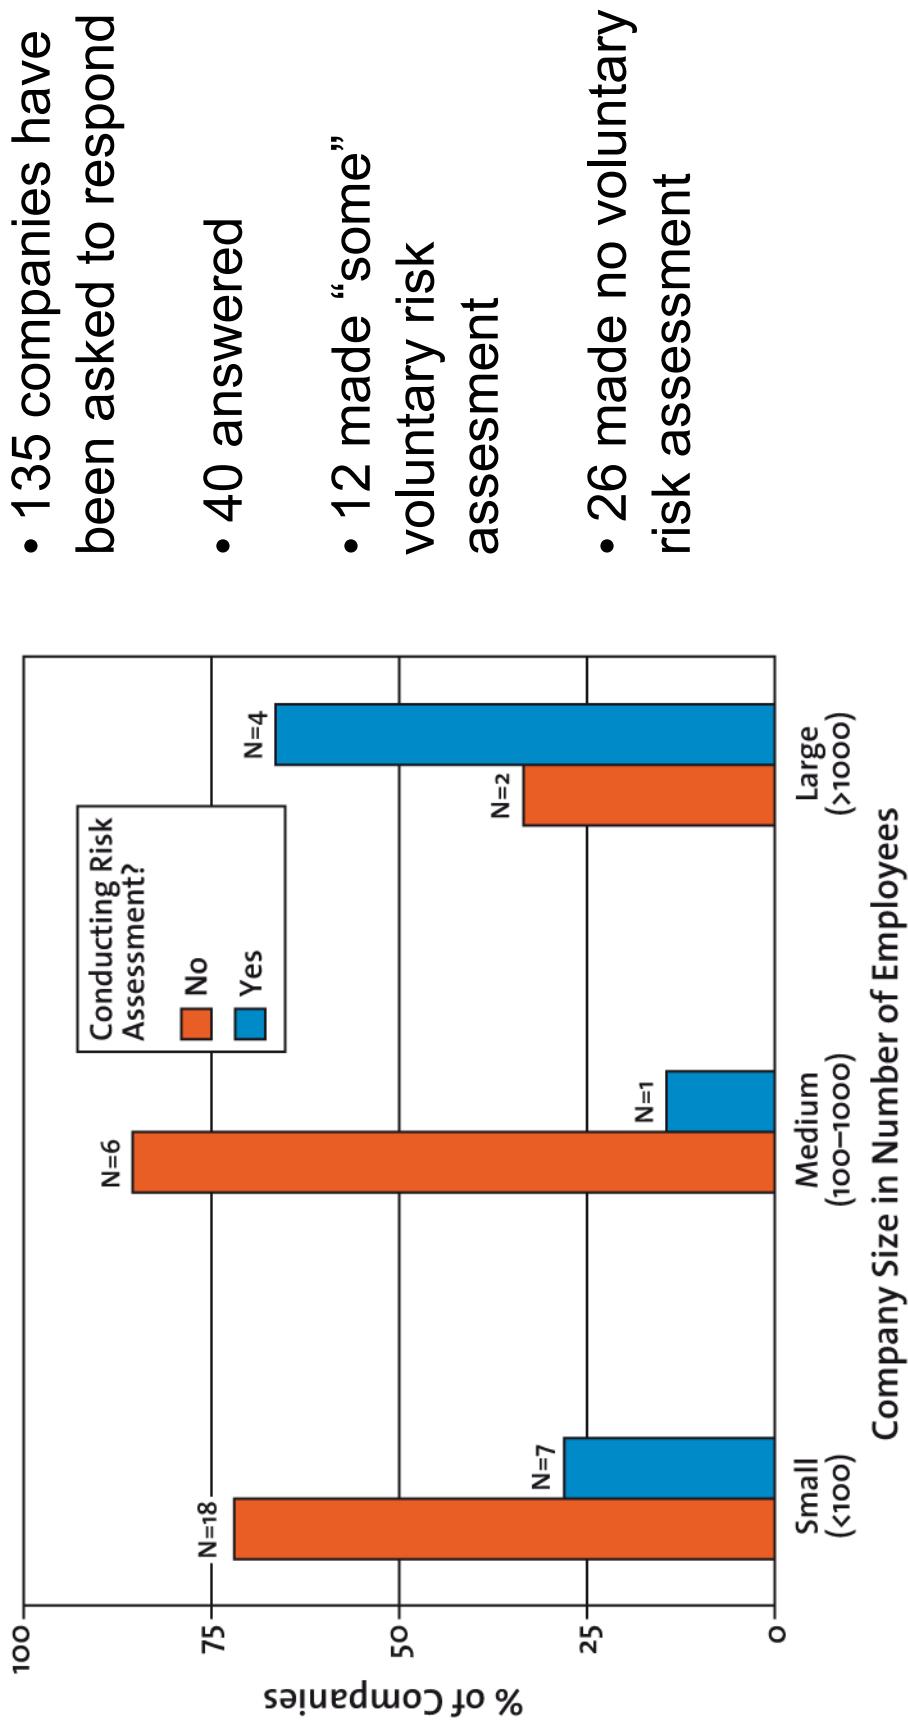

has not yet been applied (at least not quantitatively) to nano-particles.

# The Cases – Nanotech Particles

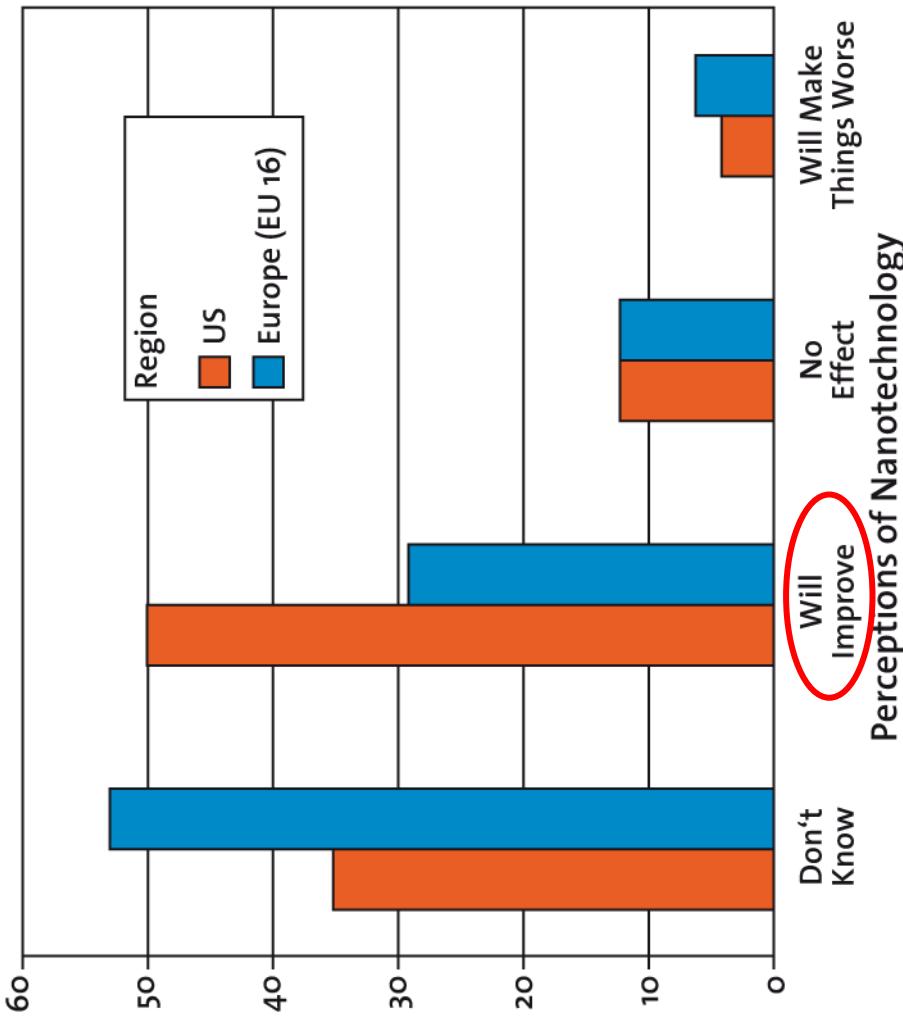

## Risk assessment of Nanotech Particles (cont.)

- Asbestos like impacts on the lung
- Engineered chemicals in their nano-particle form may have properties that are completely different from their larger physical forms and may therefore interact differently with environmental systems
- No developed guidelines exist on testing procedures. Current risk assessment methodologies may not be adequate for the case of nano-particles
- Risk **assessment** research programs started in many places of the world.

# Risk Assessments are not voluntarily done by companies

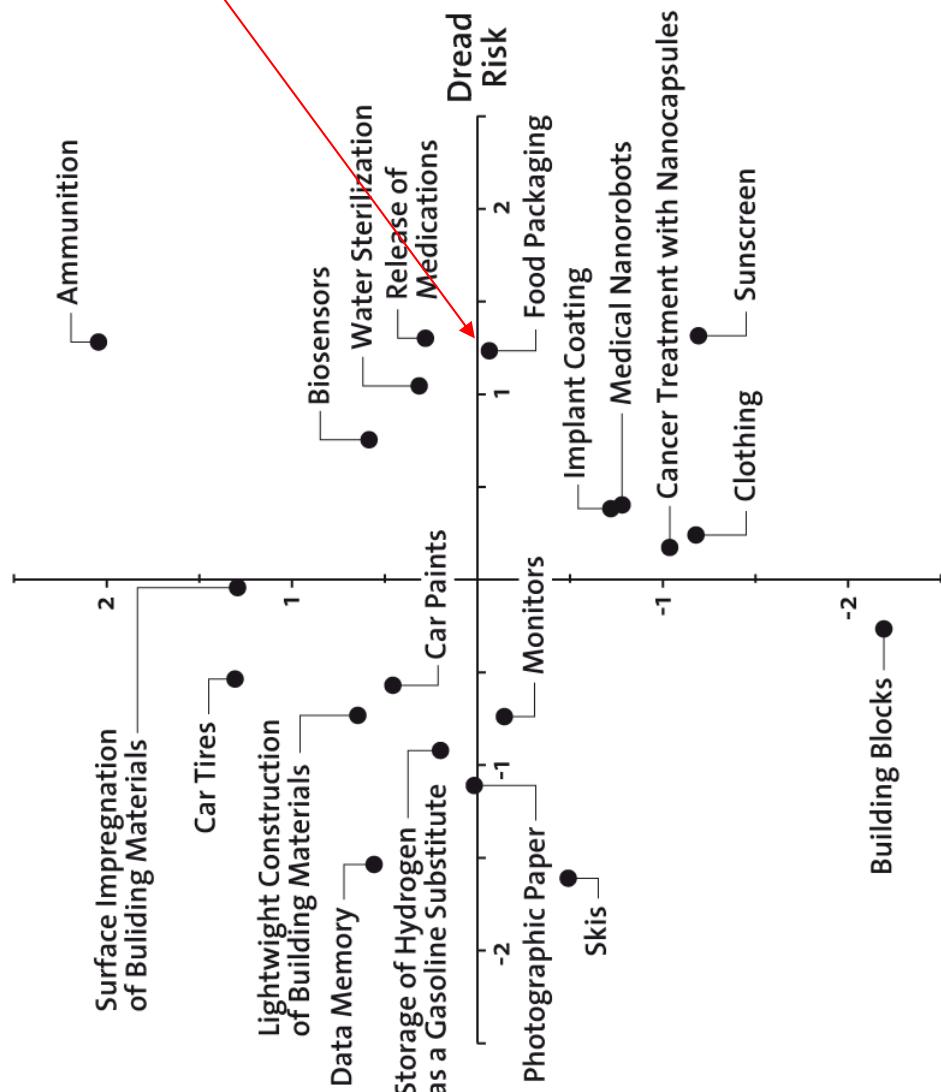

# Survey Results: People are gentle to nanotech because they expect positive effects

Gaskell et al., 2005

# Psychometric Paradigm. What applications of nanoparticles are suspected

# Summary with respect to Nanotech Particles

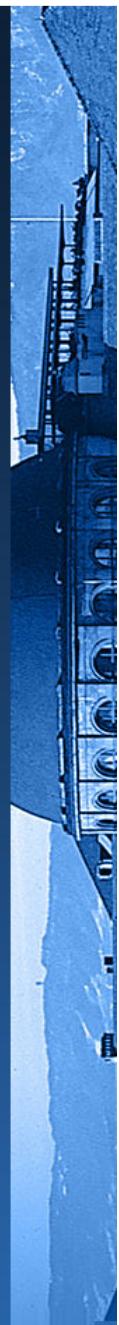

- Engineered nanotech particles may induce new, unknown health and environmental risks
- Besides plausible (asbestos like) lung damages not much is known
- Only few companies perform a volunteer risk assessment
- Perceived dreadfulness of applications and trust in governmental agencies are important factors in risk perception
- (US and European) Laypersons perceive greater risks than experts
- People get sensitive with food-products

## Four general conclusions on low risk and high public concern?

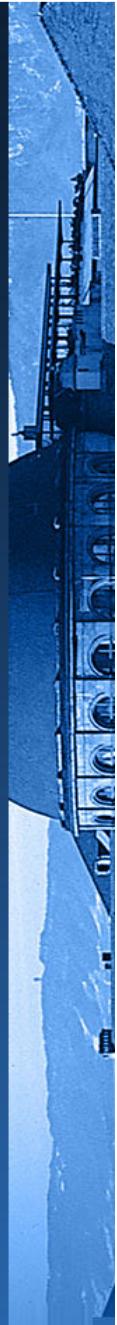

# 1. Risk assessment: We have different knowledge about different risk

- Heavy metals and POPs are considerable real risks with severe impacts on human and ecosystem health; nanotech particles might have the potential
- From a natural science perspective we have classical, measurable dose-response relationships (e.g. for heavy metals such as Cadmium) and systemic risks which consist of subtle changes of the whole system (such as POPs impacts in aquatic systems)

## 2. There are different concepts of risk

- There are different concepts of risk! (Risk is a construct!) The difference between
  - **pure risk** (just looking at the negative issues) and **speculative risk** (looking at the distribution of positive and negative results) may explain different risk judgments and thus th dissent among parties
    - Pure risk as the **expected number of deaths** and the pure risk as the **highest number of possible deaths** can explain differences among people concerned and people from an environmental protection agency
- These different concepts can be at work both in risk assessment and risk perception

### 3. Emotional concern, symbolic values etc. can lead to oversensitive risk perception of the public

- Stakeholder views (economists vs. environmentalists) are at least as important as cultures
- People are aware of risks heavy metals, POPs, nanotech particles, but none of these are (currently) **stigmatized** such as GMOs or nuclear waste
- People's intuitive risk judgments depend on
  - The "symbolic value" of the safeguard objects (see Rachel Carson's successful campaign against DDT when she proposed the effect on birds [e.g. the American eagle] or the perceived importance of safeguard objects [e.g. babies])
    - For risk judgments, emotional concern is more important than objective concern
    - Emotional concern and trust (into the public authorities, companies etc.) are most important in risk judgments

## 4. Risk assessment and risk perception are related

- Science “news” affect the public (media). And what is considered being an important safeguard at risk is determined by the public
- If the public loses trust and lacks control, risk perception can become a real problem
- Good risk assessments, good and open risk information are key issues of successful and sustainable risk management!
